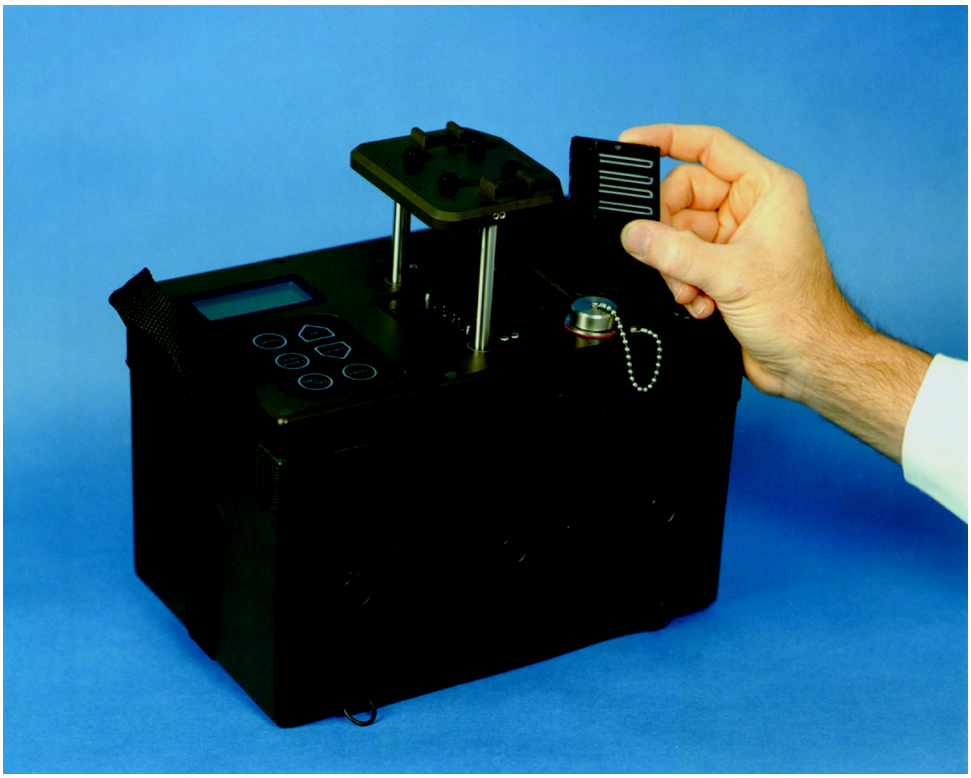
FIBER-OPTIC BIOSENSOR



NRL has developed a highly sensitive, highly selective fiber-optic biosensor. The system measures the formation of a fluorescent complex at the surface of an optical fiber. Antibodies or DNA-binding proteins on the fiber-optic surface provide the mechanism for recognizing the analyte of interest and immobilizing a fluorescent complex on the fiber. The system is particularly well-suited for detection of hazardous chemical or biological materials and has undergone extensive field testing.

Advantages include:

- Rapid detection (within minutes)
- Sensitivity (parts per billion)
- Able to detect up to four agents simultaneously by using multiple probes
- Remote detection via fiber-optic cable
- Lightweight and compact for portability; capable of battery operation
- Disposable probes with long shelf life

Applications include:

- Environmental monitoring (atmosphere, groundwater, and soil)
- Food safety
- Clinical diagnostics

Licenses are available to companies with commercial interest.
